Name: Aditi Chauhan

1. INTRODUCTION

In this group project, a Banking Management System is developed to support day-to-day banking operations using modern web technologies. The project is designed following the MERN stack architecture, where each team member contributes to a specific module. My individual contribution focuses on the frontend development, with special emphasis on admin-side dashboards, reporting features, and frontend-backend integration.

The frontend plays a critical role in presenting complex banking data in a clear and understandable manner. My work ensures that administrators can efficiently monitor banking activities, analyse daily performance, and manage accounts through a well-structured and responsive user interface.

2. FRONTEND TECHNOLOGIES USED

The frontend part of the Banking Management System is developed using the following technologies:

- React.js – Component-based library for building dynamic user interfaces
- HTML5 & CSS3 – Structure and styling of UI components
- JavaScript (ES6) – Application logic and interactivity
- Axios / Fetch API – Communication with backend REST APIs
- MongoDB (via APIs) – Backend database whose data is displayed on the frontend
- CSS Flexbox & Grid – Responsive layouts

A modular component-based approach is followed to improve maintainability and reusability.

3. FRONTEND RESPONSIBILITIES IN THE PROJECT

My responsibilities in the project include:

- Designing and developing the Admin Dashboard interface
- Implementing frontend logic for daily reports and summaries
- Integrating frontend components with backend REST APIs
- Displaying dynamic data retrieved from MongoDB
- Creating tables, cards, and status indicators for admin operations

- Ensuring responsive and user-friendly layouts

These responsibilities ensure that administrative users can manage the banking system efficiently.

4. ADMIN DASHBOARD FEATURE: DORMANT ACCOUNT IDENTIFICATION

The admin dashboard also highlights Dormant Accounts, which are accounts with no transaction activity for a long period. These accounts are marked separately to help administrators monitor inactive users and manage accounts effectively.

5. API INTEGRATION AND DATABASE INTERACTION

The frontend communicates with backend REST APIs to retrieve and display data stored in MongoDB. All dashboard data such as users, accounts, transactions, and loans are dynamically rendered based on API responses.

Loading states and basic error handling are implemented to enhance user experience

7. FUTURE SCOPE

The frontend module can be enhanced further with the following features:

- Downloadable daily reports in PDF or Excel format
- Graphical charts for transaction and account analysis
- Advanced search and filter options in admin dashboard
- Notification alerts for important admin actions
- Improved UI design with themes and animations

8. CONCLUSION

My contribution to the Banking Management System focuses on frontend development with emphasis on admin dashboards, daily reporting, and data-driven UI features. The Daily Banking Report and Dormant Account Identification features add practical value to the system while remaining easy to use and maintain.

This work demonstrates my understanding of frontend development, API integration, and real-world banking interface design.
